

**Figure 6.1**

A Bragg reflection from a particular family of lattice planes, separated by a distance  $d$ . Incident and reflected rays are shown for the two neighboring planes. The path difference is  $2d \sin \theta$ .

**Figure 6.2**

The Bragg angle  $\theta$  is just half the total angle by which the incident beam is deflected.

**Figure 6.3**

The same portion of Bravais lattice shown in Figure 6.1, with a different resolution into lattice planes indicated. The incident ray is the same as in Figure 6.1, but both the direction (shown in the figure) and wavelength (determined by the Bragg condition (6.2) with  $d$  replaced by  $d'$ ) of the reflected ray are different from the reflected ray in Figure 6.1. Reflections are possible, in general, for any of the infinitely many ways of resolving the lattice into planes.

*Über die Interferenzerscheinungen an planparallelen Platten*

**Figure 6.8**

The Ewald construction for the Laue method. The crystal and incident X-ray direction are fixed, and a continuous range of wavelengths, corresponding to wave vectors between  $k_0$  and  $k_1$  in magnitude, is present. The Ewald spheres for all incident wave vectors fill the shaded region between the sphere centered on the tip of the vector  $\mathbf{k}_0$  and that centered on the tip of  $\mathbf{k}_1$ . Bragg peaks will be observed corresponding to all reciprocal lattice points lying within the shaded region. (For simplicity in illustration, the incident direction has been taken to lie in a lattice plane, and only reciprocal lattice points lying in that plane are shown.)

Fig. 4-7 The rotating crystal method of x-ray measurement.

Fig. 4-7 The rotating crystal method of x-ray measurement.

The Ewald construction for the rotating-crystal method. For simplicity a case is shown in which the incident wave vector lies in a lattice plane, and the axis of rotation is perpendicular to that plane. The concentric circles are the orbits swept out under the rotation by the reciprocal lattice vectors lying in the plane perpendicular to the axis containing  $\mathbf{k}$ . Each intersection of such a circle with the Ewald sphere gives the wave vector of a Bragg reflected ray. (Additional Bragg reflected wave vectors associated with reciprocal lattice vectors in other planes are not shown.)

Figure 6.9

**Figure 6.10**

The Ewald construction for the powder method. (a) The Ewald sphere is the smaller sphere. It is centered on the tip of the incident wave vector  $\mathbf{k}$  with radius  $k$ , so that the origin  $O$  is on its surface. The larger sphere is centered on the origin and has a radius  $K$ . The two spheres intersect in a circle (foreshortened to an ellipse). Bragg reflections will occur for any wave vector  $\mathbf{k}'$  connecting any point on the circle of intersection to the tip of the vector  $\mathbf{k}$ . The scattered rays therefore lie on the cone that opens in the direction opposite to  $\mathbf{k}$ . (b) A plane section of (a), containing the incident wave vector. The triangle is isosceles, and thus  $K = 2k \sin \frac{1}{2}\phi$ .

**Figure 6.11**

Points in the simple cubic reciprocal lattice of side  $2\pi/a$ , for which the structure factor (6.16) vanishes, are those (white circles) that can be reached from the origin by moving along an odd number of nearest-neighbor bonds. When such sites are eliminated, the remaining sites (black circles) constitute a face-centered cubic lattice with cubic cell of side  $4\pi/a$ .

**Figure 6.12**

The body-centered cubic lattice with cubic cell side  $4\pi/a$  that is reciprocal to a face-centered cubic lattice with cubic cell side  $a$ . When the fcc lattice is that underlying the diamond structure, then the white circles indicate sites with zero structure factor. (The black circles are sites with structure factor 2, and the gray ones are sites with structure factor  $1 \pm i$ .)
